Abstract

The studies were conducted in the period from 06.02.2011 to 06.07.2011 in the conditions of the State Enterprise "Moldsuinhibrid" for pig breeding and hybridization, using Landrace breed pigs, selected on the basis of analogues [9]. Four groups of pigs of ten heads each were formed. The piglets in the control group were fed the basic feed, and the ration for the experimental groups EG₁, EG₂ and EG₃, was supplemented with the adsorbent Primix-Alfasorb at the level of 0.2, 0.4 and 0.6 kg / t respectively. It was established that the addition of the adsorbent Primix-Alfasorb into the mixed fodder for breeding pigs contributed to the increase of live weight gain during the periods of breeding; after the experiment the body weight was greater in groups EG₁, EG₂ and EG₃ by 8.66, 5.77 and 7.88% compared with the control group. The use of the adsorbent Primix-Alfasorb resulted in the improved fodder conversion; the fodder consumption to increase the body weight decreased in the experimental groups by 6.25 - 9.69% in comparison with the control group. The optimal level of the adsorbent Primix-Alfasorb in the mixed fodder for breeding pigs was 0.2 kg / t.

Key words: mycotoxins, pigs, sorbents, mixed fodder

INTRODUCTION

Mycotoxins continue to be priority natural contaminants of feedstuffs and food in modern animal husbandry. The reason of mycotoxicosis may be a variety of mushrooms, contaminating fodder plants and fodder during the violation of cultivation and storage technology. During mycotoxicosis cardiovascular and immune systems suffer particularly strongly. When the immune system is out of order the possibility of transmission of viral and bacterial infections to animals increases, and the effectiveness of specific prevention is sharply reduced [1, 3, 5].

Currently, most researchers recognize the concept of synergy in the action of mycotoxins on the body, and therefore believe that safe levels of mycotoxins do not exist [2, 7, 8]. Symptoms of typical mycotoxicosis in pigs are often observed, even when tests show only a slight presence of mycotoxins in animal fodders [12].

The variety of ingredients in mixed fodders increases the possibility of multiple mycotoxins contamination while reducing the risk of high concentrations of mycotoxins, because the content of any of the fodder components in the composition of the diet is low. However, the presence of several mycotoxins in the fodder can lead to toxicological synergy that would increase the severity of mycotoxicosis [11].

The variety of epizootiology, the clinical presentation and severity of mycotoxicosis depend on the number of toxins which have got into the body, the duration of its receipt, the biological and chemical activity of the toxins, the age, species and individual differences, the state of the body strength, and the environmental conditions. Therefore, in different places and at different times mycotoxicosis manifestation can differ significantly [13].

The absorption of toxins from the digestive tract is prevented by the enter sorbents. One of these is the highly dispersed adsorbent Primix-Alfasorb. The preparation is harmless, has a high adsorption capacity, and does not contain impurities.

MATERIAL AND METHODS

The studies were conducted in the period from 06.02.2011 to 06.07.2011 at the State Enterprise "Moldsuinhibrid" for pig breeding and hybridization.

The object of the study was pure-bred two-months-old pigs of Landrace breed. By the principle of analogues [9], four groups of pigs of ten heads each were formed (Tab. 1).

Table 1 The scheme of the scientific experiment

Groups	Number of animals per group, head	Feeding features
CG	10	Basic mixed forage (BMF)
EG ₁	10	BMF + 0.2 kg/t Primix-Alfasorb
EG ₂	10	BMF + 0.4 kg/t Primix-Alfasorb
EG ₃	10	BMF + 0.6 kg/t Primix-Alfasorb

During the experiment, the animals were kept in groups. The feeding was carried out using mixed fodders which were manufactured at the factory of the company. The piglets of the control group were fed the basic mixed fodder, and the features and differences in the feeding of pigs in the experimental groups was that their main mixed fodder was supplemented with the adsorbent Primix-Alfasorb at different levels.

To characterize the pigs growth and development in different groups the live weight, the daily gain in body weight, and the absolute and relative growth rate were determined by weighing them at birth, at the weaning at 35 days, in 2 months and then by

periods of growth. The data obtained in the experiment were processed using the method of variation statistics in EXCEL [4, 10].

RESULTS AND DISCUSSIONS

The scientific and economic trial was divided into the preparatory period of 10 days and the reference period, which in its turn was divided into three periods of breeding. The feeding in the scientific and economic experiment was carried out in accordance with the norms of pig feeding [6] taking into account the body weight and age (Tables 2, 3).

The determination of the pigs live weight via individual weighing according to the trial periods indicated (Table 4) that under the influence of the addition of the sorbent Primix-Alfasorb by the end of the first period of breeding their weight increased in EG₁, EG₂, EG₃ compared to CG respectively by 14.77%, 4.61% and 13.26%, i.e. the weight was the most higher in EG₁ in which the pigs

received an addition of the preparation at the level of 0.2 kg/t.

The total weight gain of the animals at the end of the second period of breeding in the control group was 14.50 kg, whereas in the experimental groups (EG₁, EG₂, and EG₃) the increase in the body weight was higher respectively by 16.1 kg, 14.96 kg and 15.90 kg.

During the whole trial the live weight of the breeding piglets in groups EG₁ and EG₃ was 102.24 and 101.50 kg, and it was greater in comparison with the CG by 8.66 and 7.88%

respectively. The highest average daily gain, in correspondence with the periods of breeding and during the whole trial, was observed in the group treated with the addition of the sorbent

Primix-Alfasorb at the level of 0.2 kg/t, and amounted to 0.517, 0.519 and 0.646 g, and at conformably to the breeding periods it the end of the trial to 0.595 g.

The data on the quantity of eaten fodder by the animals during the trial allowed calculating the total average amount of fodder consumed in each group (Table 6).

Table 6 Fodder consumption by the pigs in the trial

Average quantity of fodder consumed in each group, kg:	Groups			
	CG	EG ₁	EG ₂	EG ₃
during the first breeding period	419.25	408.14	419.45	434.35
during the second breeding period	448.54	447.54	449.39	457.15
during the third breeding period	1770.5	1755.1	1758.2	1766.0
during the whole trial	2638.3	2610.8	2627.0	2657.1

On the basis of the results on the general increase in animal body weight and the data on the fodder the animals had consumed, the fodder consumption per kilogram of weight gain were calculated, which amounted to 3.20, 2.89, 3.00 and 2.96 kg respectively in groups CG, EG₁, EG₂ and EG₃, i.e. the consumption was lower in the groups which had received fodder supplemented with the adsorbent Primix-Alfasorb.

CONCLUSIONS

- The addition of the adsorbent Primix-Alfasorb into the fodder for breeding pigs has contributed to the increase of live weight gain during the rearing periods, and during the whole experience it was greater in groups

of EG₁, EG₂ and EG₃ by 10.97, 3.17 and 9.66% in comparison with the control group.

- The supplementation of the mixed fodder for piglets with the adsorbent Primix-Alfasorb causes the reduction of fodder consumption for the live weight gain on the average from 6.25% to 9.69%.

- The optimal level of the adsorbent Primix-Alfasorb in the mixed fodder for breeding piglets is 0.2 kg / t.

ACKNOWLEDGEMENTS

The authors wish to express their gratitude for the generous and expert assistance provided by the staff of the State Enterprise "Moldsuinhibrid" and the Scientific Production Enterprise "Ariadna".
